→ MACHINE LEARNING

MULTIPLE LINEAR REGREEION

▼ STEP-0 Import libraries

```
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt
```

▼ Step 1 Import Dataset

```
import pandas as pd
df = pd.read_csv("ml_data_salary - Copy.csv")
df.head()
```

	age	distance	YearsExperience	Salary
0	31.1	77.75	1.1	39343
1	31.3	78.25	1.3	46205
2	31.5	78.75	1.5	37731
3	32.0	80.00	2.0	43525
4	32.2	80.50	2.2	39891

▼ Step 2 Define dependentent and independentent variables

```
X = df[["age","distance", "YearsExperience"]]
y = df["Salary"]
```

▼ Step 3 Fit Linear Regression Model

```
from sklearn.linear_model import LinearRegression
model = LinearRegression()
model = model.fit(X, y)
model

* LinearRegression
    LinearRegression()
model.coef_
```

array([-3.00216193e+15, 1.18788781e+15, 3.24424072e+13])

▼ Step 4 Evaluating Model Fitness

▼ STEP 5 Prediction of unknown values

```
model.predict([[31.1,77.75,1.1]])

/usr/local/lib/python3.10/dist-packages/sklearn/base.py:439: UserWarning: X does not have valid feature names
    warnings.warn(
    array([36209.375])
```

Step 6 Measure Accuracy

```
import numpy as np
from sklearn.model_selection import train_test_split
from sklearn.linear model import LinearRegression
from sklearn.metrics import r2_score
# Generate sample data
np.random.seed(42)
X = np.random.rand(100, 5) # Features (100 samples, 5 features)
y = np.random.rand(100)
                           # Target values
# Split the data into training and testing sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)
# Train the linear regression model
model = LinearRegression()
model.fit(X_train, y_train)
# Make predictions on the test set
y_pred = model.predict(X_test)
# Calculate the R-squared score as a measure of accuracy
accuracy = r2_score(y_test, y_pred)
print("Accuracy:", accuracy)
```

C→ Accuracy: -0.6207587492946209
